Creational patterns

In software engineering, creational design patterns are design patterns that deal with object creation mechanisms, trying to create objects in a manner suitable to the situation. The basic form of object creation could result in design problems or added complexity to the design. Creational design patterns solve this problem by somehow controlling this object creation.

- **Abstract Factory**
  Creates an instance of several families of classes

- **Builder**
  Separates object construction from its representation

- **Factory Method**
  Creates an instance of several derived classes
- **Object Pool**
  Avoid expensive acquisition and release of resources by recycling objects that are no longer in use

- **Prototype**
  A fully initialized instance to be copied or cloned

- **Singleton**
  A class of which only a single instance can exist

Rules of thumb

1. Sometimes creational patterns are competitors: there are cases when either **Prototype** or **Abstract Factory** could be used profitably. At other times they are complementary: **Abstract Factory** might store a set of **Prototypes** from which to clone and return product objects, **Builder** can use one of the other patterns to

implement which components get built. **Abstract Factory**, **Builder**, and **Prototype** can use **Singleton** in their implementation.

2. **Abstract Factory**, **Builder**, and **Prototype** define a factory object that's responsible for knowing and creating the class of product objects, and make it a parameter of the system. **Abstract Factory** has the factory object producing objects of several classes. **Builder** has the factory object building a complex product incrementally using a correspondingly complex protocol. **Prototype** has the factory object (aka prototype) building a product by copying a prototype object.

3. **Abstract Factory** classes are often implemented with **Factory Method**s, but they can also be implemented using **Prototype**.

4. **Abstract Factory** can be used as an alternative to **Facade** to hide platform-specific classes.

5. **Builder** focuses on constructing a complex object step by step. **Abstract Factory** emphasizes a family of product objects (either simple or complex). **Builder** returns the product as a final step, but as far as the **Abstract Factory** is concerned, the product gets returned immediately.

6. **Builder** is to creation as **Strategy** is to algorithm.

7. **Builder** often builds a **Composite**.

8. **Factory Method**s are usually called within **Template method**s.

9. **Factory Method**: creation through inheritance. **Prototype**: creation through delegation.

10. Often, designs start out using **Factory Method** (less complicated, more customizable, subclasses proliferate) and evolve toward **Abstract Factory**, **Prototype**, or **Builder** (more flexible, more complex) as the designer discovers where more flexibility is needed.

11. **Prototype** doesn't require subclassing, but it does require an Initialize operation. **Factory Method** requires subclassing, but doesn't require Initialize.

12. Designs that make heavy use of the **Composite** and **Decorator** patterns often can benefit from **Prototype** as well.

Support our free website and own the eBook!

- 22 design patterns and 8 principles explained in depth
- 406 well-structured, easy to read, jargon-free pages
- 228 clear and helpful illustrations and diagrams
- An archive with code examples in 4 languages
- All devices supported: EPUB/MOBI/PDF formats
